WDM is a technology that enables various optical signals to be transmitted by a single fiber. Its principle is essentially the same as Frequency Division Multiplexing (FDM). That is, several signals are transmitted using different carriers, occupying non-overlapping parts of a frequency spectrum.

Optical networks (in which data is converted to bits of light called photons and then transmitted over fiber) are faster than traditional networks (in which data is converted to electrons that travel through copper cable) because photons weigh less than electrons, and further, unlike electrons, photons do not affect one another when they move in a fiber (because they have no electric charge ...

Summary This chapter presents the flexible and scalable optical transport network architecture called elastic optical network (EON). To meet future Internet traffic requirements, a novel EON architecture with flexible data rate and spectrum allocation, high resource efficiency, and low power consumption is required.

WDM Optical Network. Wavelength Division Multiplexing (WDM) is a technology which multiplexes a number of optical carrier signals onto a single optical fiber by using different wavelengths (i.e., colors) of laser light. This technique enables bidirectional communications over one strand of fiber, as well as multiplication of capacity.
